WhatsApp Backup Agent — External Hosting Migration Plan (Deferred Task)

Prepared for: Tom Ugbodaga, Shareholder & CEO

Status: DOCUMENTED, NOT YET BUILT — execute once revenue lands

Date: August 23, 2026

The Gap This Closes

The existing WhatsApp backup agent (function: `whatsappBackupAgent`) works and has been tested — it holds real conversation memory per phone number and replies automatically once Twilio's webhook points at it. But it is still a Base44 backend function. If Base44 itself goes fully offline, this bot goes down with it. It currently protects against this specific agent conversation breaking or running out of credits — not against a total Base44 outage.

The Fix

Move the exact same logic (OpenAI gpt-4o-mini call + persistent memory + company system prompt) off Base44 and onto a small independent server. Twilio's webhook would then point at that external URL instead of a `base44.app` one. This makes the WhatsApp number itself survive a full Base44 death, matching the same independence already achieved for

GitHub-hosted backups and the Gemini clone.

What It Needs (when you're ready)

1. A small external host

Render.com or Railway.app — both have a free tier for light traffic, paid tiers (~\$5-7/month) if the free tier's sleep/cold-start behaviour is too slow for real-time WhatsApp replies.

2. A rebuilt lightweight webhook endpoint

Same logic as whatsappBackupAgent (accept Twilio's form-encoded From/Body, reply with TwiML) rewritten as a small standalone Node.js or Python app, not a Base44 function.

3. Persistent memory storage

Since it can no longer use the Base44 BackupAgentMessage entity, memory would move to a lightweight external store — e.g. a free-tier hosted SQLite/Postgres (Render/Railway both offer this) or even a flat file if traffic stays low.

4. Company knowledge baked in

Same as today: AGENT_CLONE_777.md content baked into its system prompt so it answers with identical facts and personality.

5. An OpenAI API key

Already required today for the existing agent; carries over unchanged.

6. Twilio webhook re-point

Once the new endpoint is live and tested, update the Twilio WhatsApp sandbox/number's webhook URL to the new external address instead of the current base44.app one.

Migration Steps (once approved to proceed)

1. Rebuild the whatsappBackupAgent logic as a standalone Node.js/Express or Python/Flask app.
2. Deploy it to Render or Railway free tier first, to validate before spending anything.
3. Wire up persistent memory (hosted Postgres/SQLite on the same platform).
4. Bake in AGENT_CLONE_777.md as the system prompt.
5. Test end-to-end with a temporary Twilio sandbox number first.
6. Once verified, re-point the real Twilio WhatsApp number's webhook to the new external URL.
7. Keep the original Base44 function as a fallback for a transition period, then retire it.

Why This Is Deferred, Not Skipped

Per standing instruction, non-critical spend is on hold until revenue lands. The current Base44-hosted version already

works for the realistic near-term risk (this agent/conversation breaking); the full Base44-outage scenario is a lower-probability, higher-effort fix best tackled once there's budget for the ~\$5-7/month external host without it being a stretch.

Recommended trigger to build this: once first revenue lands, same trigger as the Agent Zero setup.
